13. ABSTRACT (Maximum 200 words)  Testing of the Responder CSM® Level A suit ensemble was conducted according to MIST test guidelines promulgated by the Joint Services Lightweight Integrated Suit Technology (JSLIST) test working group. This testing was conducted with the chemical agent simulant methyl salicylate (MS) to determine the protective capability of the suit against chemical warfare agents (CWA). This testing was to fill in data gaps on commercial protective suits (they are not certified by either NIOSH or OSHA for CWA) so they can be used by emergency personnel at sites that have been infiltrated by terrorist assailants with unknown chemical and/or biological weapons of mass destruction. The testing showed that the Responder CSM® suit, when worn in the Level A mode with self-contained breathing apparatus (SCBA), provided wearers with an overall protection factor of 1686.

**Man In Simulant Testing (MIST) of Domestic Preparedness Suits  
Kappler Model 42483, Responder CSM® Level A Suit**

**1. INTRODUCTION**

This testing has been performed to evaluate the protective capability of commercially available chemical suits. Most of the suits have been tested for resistance to various commercial chemicals, but have not been tested to determine the protection they provide against chemical warfare agents. The Man In Simulant Testing (MIST) is a set of tests designed to evaluate the protection provided by a complete protective garment/mask/boot/glove ensemble against chemical warfare agents through the use of non-toxic simulants. Complete modelling has been performed by Fedele and Nelson<sup>1</sup> to determine an appropriate method for evaluation of the protection based upon a Body Region Hazard Analysis. This method uses actual skin adsorption data on agents and simulants and is modelled to predict the Minimum Required Exposure Dosage (MRED) to which an individual must be exposed to in order to produce end-point reactions in the body for systemic (nerve agent) and localized (mustard) exposure to agents.

This report outlines testing performed on the commercially available Kappler Model 42483 suit by the Respiratory and Collective Protection Team of the U.S. Army Edgewood Research, Development and Engineering Center (ERDEC),\* Chemical & Biological Defense Command,\*\* in the MIST test chamber in August 1997. Similar testing was conducted on the Kappler First Responder® suit in July of 1995<sup>2</sup> when this suit was evaluated for possible use by emergency personnel in the event of a chemical agent release from the Tooele Army Depot's demilitarization facility. The testing described in this report consisted of four trials, each involving two to four test subjects. A short description of the suit tested is given below.

**Description of the Responder CSM® Level A Suit.**

The Kappler model 42483 Responder CSM® Level A Suit is a gastight protective suit that completely encapsulates the wearer. The garment and booties of the suit are constructed from the Responder CSM™ multi laminate film fabric material; the visor is constructed of 5 mil FEP/40 mil polished PVC material. The suit contains butyl rubber gloves (25 mil, MIL-G-12223, Type II, Gloves, protective, toxicological Agent) that are sealed into place at the wrists and also contains sealed leg booties and a hood that completely encapsulates the head and respiratory protection. All suits were tested when received to ensure that they met the test protocol standards. Testing involved a visual inspection for damage followed by pressurization of the suits with air. This involved using a pressure of 3 inches water guage (iwg) for three minutes, reducing the pressure to 2 iwg, and then waiting an additional three minutes. If the pressure does not drop below 1.6 iwg after this time the suit passes this test. The respiratory protection used with this suit is the Self-Contained Breathing Apparatus (SCBA) with a one-hour air tank that is worn on the back. Standard rubber Toxicological Agent Protective (TAP) boots are also worn with the suit. A picture of a test subject wearing the Responder CSM® suit is shown in Figure 1; Figure 2 shows a test subject wearing the SCBA.

## 2. SCOPE

This testing was conducted according to guidelines set forth by the Joint Services Lightweight Integrated Suit Technology (JSLIST) working group, specifying test methods capable of accurately measuring a protection factor (PF) greater than 1,000. The maximum PF that could accurately be measured in this testing was around 10,000. This involved the use of passive sampling devices mounted beneath the clothing of the test subjects to sample the vapors at a rate consistent with the body's uptake rate of agent, as determined in the JSLIST research study on passive sampling devices<sup>3</sup>. The sizes used for this testing were matched to the size of the test subject, a total of fourteen suits were used: three small, nine medium, and two large sizes. Similar testing was conducted on the Kappler First Responder<sup>®</sup> suit in July of 1995<sup>2</sup> when this suit was evaluated for possible use by emergency personnel in the event of a chemical agent release from the Tooele Army Depot's demilitarization facility.

In each of four trials, test subjects dressed in the Responder CSM<sup>®</sup> protective ensemble and were exposed to a high concentration of methyl salicylate (MS) vapor. Four subjects were tested in each trial, except in trial 3, where only two were tested. The JSLIST working group selected this simulant for the agent mustard (HD) for use in testing under the JSLIST program. Each trial exposed the test subjects to an MS concentration of 50 mg/m<sup>3</sup> in a chamber for a total of 30 minutes. The test subjects performed a series of exercises while exposed to the MS vapors. Vapor concentrations were measured at several locations beneath the suit with passive sampling devices (PSDs). The PSDs contained the solid adsorbent Tenax, which the JSLIST working group had chosen as the best adsorbent for use with MS<sup>4</sup>. This testing showed that the Responder CSM<sup>®</sup> Level A suit configuration exhibited an overall protection factor (when used for brief time periods of 30 minutes) that was very high (when compared to non-Level A suit ensembles).

The configuration of the protective suit ensemble tested was as follows. The test subjects wore shorts and t-shirts underneath the Responder CSM<sup>®</sup> suit. PSDs were affixed to this clothing or directly on skin areas. Self Contained Breathing Apparatus was put on and then the Responder CSM<sup>®</sup> suit was donned and sealed up according to the manufacturer's specifications. All subjects were trained in the use of the suit according to the manufacturer's use instructions prior to testing.

## 3. TEST EQUIPMENT AND PROCEDURES

### 3.1 Test Facility.

The tests were conducted in the MIST test facility in building E5354 in the Edgewood Area of Aberdeen Proving Ground, MD. The exposure chamber is 40 ft by 20 ft by 14 ft high and contains an evaporative-blower vapor generator controlled by a data acquisition system (DAS) with feedback concentration readings generated by a Foxboro Miniature Infra-Red Gas Analyzer (MIRAN<sup>®</sup>). The challenge concentration in the chamber was measured during the exposure period with two MIRAN<sup>®</sup>s. The location of the MIRAN<sup>®</sup>'s sampling point were as follows: one sample was taken in the front of the chamber right in the area where the subjects performed the exercises, the other sample

point was in the rear of the chamber. All MIRAN<sup>©</sup> readings were recorded by the DAS and the average of the two was used in the data analysis.

A four-stage clean-room was erected in a bay area adjacent to the exposure chamber and was occupied by test subjects during application and removal of the sampling devices. This clean-room consisted of two airlocks and two 16-ft enclosures of the U.S. Army M28 shelter system. The enclosures, made of a chemically resistant plastic material, were pressurized with filtered air from Nuclear, Biological, and Chemical (NBC) filter units of the M28. A 600 cfm unit was used to pressurize the clean room area (Enclosure 4 of Figure 3), and two 200 cfm units were used to pressurize the doffing room area (Enclosure 2 of Figure 3), for a total clean airflow of 1000 cfm. A layout of the test area and apparatus is shown in Figure 3.

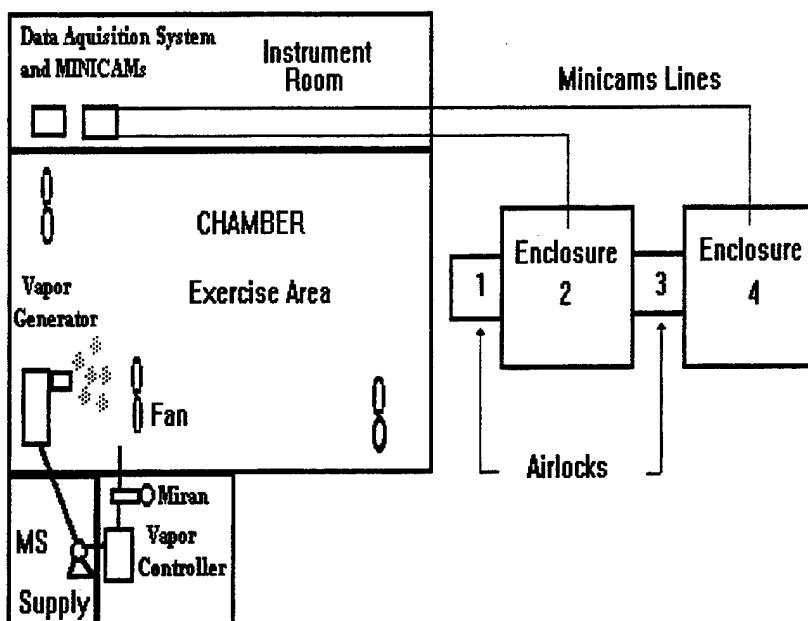

Figure 3. Chamber and Clean-Room Layout

### 3.2 Air Sampling Devices for Measuring Concentration Inside Suit.

PSDs developed by the Natick Research, Development and Engineering Center (NRDEC)<sup>\*</sup> were used to sample for MS vapors beneath the suit. The Natick sampler (shown in Figure 4) is the passive sampler used in this testing and has been approved by the JSLIST committee for sampling individual protective equipment suits. This PSD contains the solid adsorbent material Tenax<sup>®</sup> TA in a small plastic pouch and samples air by capturing the MS vapors onto the adsorbent material. This device samples the air beneath the suit by diffusion (molecular transport) with the rate of diffusion into the adsorbent controlled by the exposed layer of polyethylene film. The sampling rate for the lot of PSDs used in this testing was determined experimentally; the average rate was found to be 14.6 ml/min with a standard deviation of 0.13 ml/min. The adsorption velocity, or uptake rate, of the PSDs (sampling rate divided by the effective sampling surface area of 3.78 cm<sup>2</sup>) was 3.86 cm/min. This adsorption velocity is very similar to the skin's adsorption rate of chemical agents.

\*Now known as the U.S. Army Soldier Systems Center (SSC).

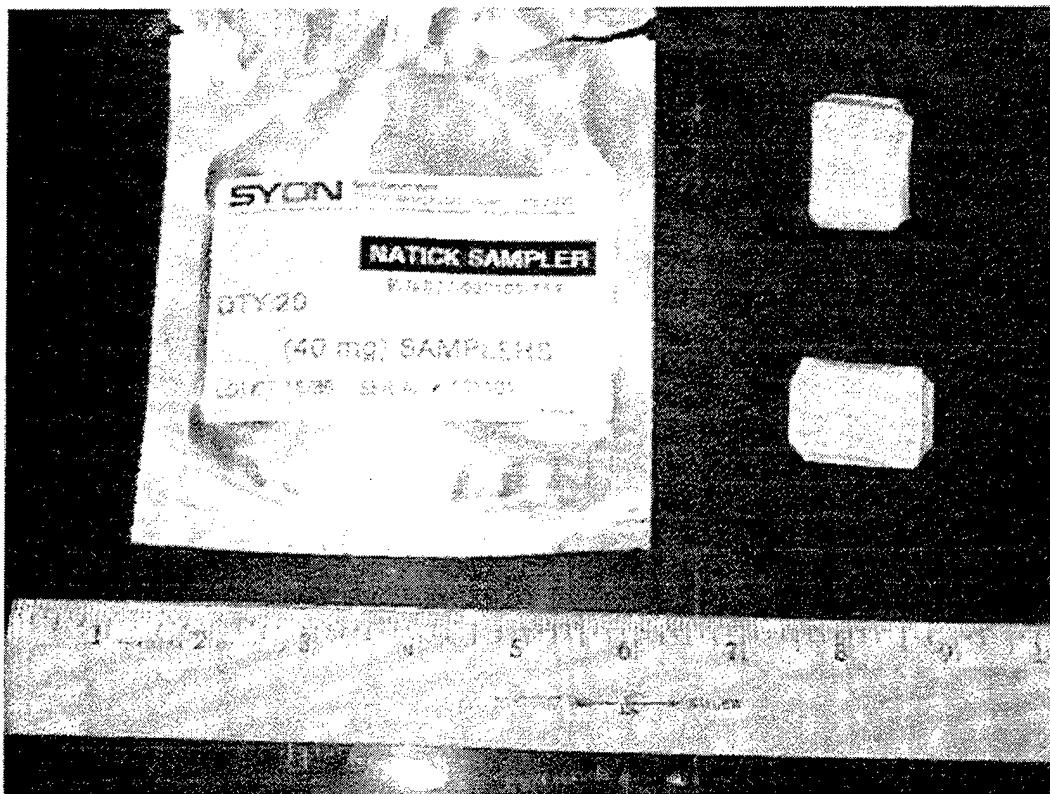

Figure 4. Passive Sampling Device Developed by the NRDEC.

The PSDs were handled with specific procedures to minimize the potential for contamination. The filter units that pressurized the clean room areas were run overnight to make sure that no trace levels of MS were present during the testing. The concentration in the clean room where the PSDs were applied to the subjects was monitored throughout the entire test period. Test technicians who worked in the clean room area washed their hands prior to handling any PSDs and were not allowed to come into any contact with the MS vapor generation equipment. They were applied to test subjects in the fourth stage of the clean-air room as the subjects put on the suit and were also removed in the fourth stage at the completion of each trial. After removing the PSD, the plastic pouch of the patch samplers was cut with a razor knife (on one end), and a sorbent tube connected to a vacuum pump was used to remove the adsorbent. One end of the tube was connected by hose to the vacuum pump and the other end was inserted into the opening of the PSD to draw out the loose sorbent. A fine mesh gauze screen was then inserted into the sorbent tube (with a special gauze loading rig) and analytical end caps were placed on both ends of the tube to preclude contamination of the sample. The tube ID was recorded to ensure accurate PSD sample identification. The tubes were then analyzed with a flame ionization detector (FID) on the Perkin Elmer Autosystems Gas Chromatograph (GC) and the ATD-400 thermal tube desorber according to guidelines determined in the JSLIST research study<sup>5</sup>. Background samples were also analyzed.

### 3.3

### Applying PSDs to Test Subjects.

The PSDs were placed at 10 locations beneath the Responder CSM® suit of each test subject, as listed below and depicted in Figure 5. They were placed either directly on the skin at these locations or on top of the underclothing (T-shirts and shorts).

- (1) Center of back, between shoulder blades
- (2) Center of chest (3 duplicate PSDs used at this location)
- (3) Center of back, lumbar, at upper buttocks
- (4) Left axillae, on ribs
- (5) Right upper arm, outer dorsum
- (6) Right lower arm, outer dorsum
- (7) Center of abdomen, low, into the groin area
- (8) Mid-right, outer thigh
- (9) Mid-right, outer lower leg
- (10) Neck

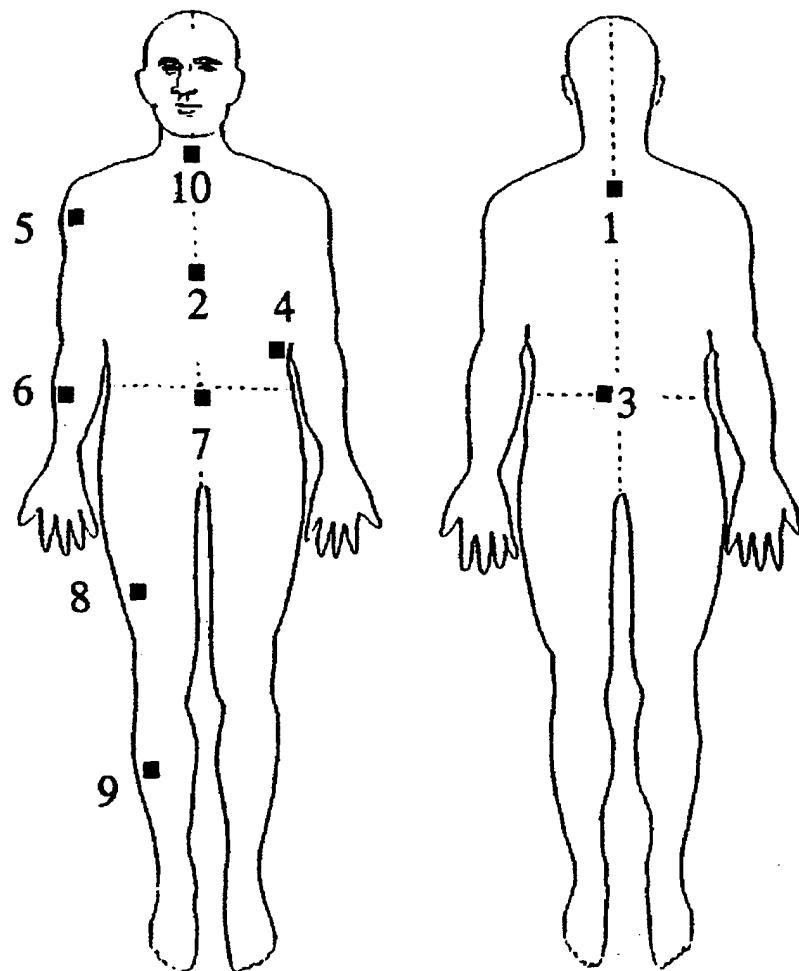

Figure 5. PSD Sample Locations.

The following procedures were used to apply the PSDs to test subjects to ensure minimum potential for contamination and allow measurement of the background levels of simulant during the analysis.

Dressing took place in the fourth (cleanest) stage of the clean room enclosure. Subjects operated in pairs during the testing because of the limitation of having no more than two people in the airlock at one time during purge operations upon re-entry to the clean room areas. Test subjects dressed in gym shorts and T-shirts before entering the clean room. When they entered the clean room, they were given new suits, SCBA mask, and overboots (which had been pre-positioned in the clean room). The PSDs, sealed in appropriate containers, and data forms were also pre-positioned.

The PSDs were removed from the storage containers and placed on the subjects at the 10 designated locations. The PSDs, which have adhesive backing, were applied directly to the skin, or to the gym shorts or T shirt (if worn). The identification number of each PSD was recorded for each location.

Once initiated, the application of the PSDs was completed as rapidly as possible. Normal application of samplers took about two minutes. Then the SCBA mask was donned, a one-hour tank for the SCBA was worn on the back, and the Responder CSM® suit was donned and sealed completely. Each subject was checked to ensure proper closure and fit of all of the gastight zipper closure and an exterior sampler was placed on the outside of the suit. The subjects then proceeded out the airlock and entered the exposure chamber. This total procedure generally took between five and ten minutes.

### **3.4 Procedure for Challenging the Suit.**

The test involved a controlled sequence of steps performed to keep the samplers free of background contamination and ensure accuracy of the results. The procedure is described below.

Subjects were briefed on the test procedures and entered the clean room, enclosure 4 in Figure 3, to have the passive samplers applied and don the suit ensemble.

Once dressed, the subjects passed through the transition airlock (enclosure 3 of Figure 3), doffing room (enclosure 2 of Figure 3) and exited through the entry/exit airlock (enclosure 1 of Figure 3). The subjects were met by a test technician who escorted them into the chamber and recorded the time of entry.

The chamber was prepared by bringing the MS concentration to 50 mg/m<sup>3</sup> before the subjects exited the clean room. Temperature, relative humidity, and concentration readings in the chamber and in both clean-air rooms were recorded on the DAS.

Once inside the chamber, subjects performed the activities listed in Table 1. Each of these exercises was performed twice during the 30-minute exposure interval. Subjects rested for about one minute after each exercise.

Table 1. Exercise Regimen

<u>Exercise</u>	<u>Time/Repetitions</u>
Stationary run	1 minute
Jumping jacks	2 times
Trunk twister	2 times
Bend and reach	2 times
Back stretcher	2 times
Bent knee leg lifts (left and right)	10 times
Vertical reach and grasp (left and right)	1 minute
Lifting box from ground to table and return	2 times
Squat down, kneel on one knee	3 times

### **3.5 Procedures for Removing PSDs.**

Because the outer garments desorb significant amounts of MS in a clean area after prolonged exposure to high concentrations of vapor, doffing took place in stages in the clean room with the following procedures.

After completing the 30 minute exercise, the subjects were escorted from the chamber and processed into the clean room in four stages (see Figure 3):

- **Stage 1** -- Entry/exit airlock. The subjects exited the chamber, entered the 4 ft by 4 ft airlock (enclosure 1), and set the purge timer for 5 minutes. They remained fully dressed while airflow through the airlock purged any vapor brought in with them. This period also allowed for some desorption of MS vapor from the outer surfaces of the ensemble.
- **Stage 2** - Once inside this 16 ft by 20 ft shelter (enclosure 2), each subject removed their ensemble with the assistance of a technician. Suits, overboots, and masks were placed in plastic bags to minimize the quantity of MS introduced. The subjects proceeded without delay to the next stage for removal of the PSDs. This process was completed in approximately 2 minutes.
- **Stage 3** - Transition airlock. In this 4 ft by 4 ft airlock (enclosure 3), the subjects proceeded without delay to the final stage to remove the PSD samplers.
- **Stage 4** - In this 16 ft by 20 ft shelter (enclosure 4), the PSDs were removed from the subjects and placed on data sheets according to their position on the body of the subject. The subjects then exited the clean room through the transition airlock. Adsorbent was transferred from the passive samplers to individually numbered sorbent tubes. The sorbent tubes were capped to preserve each sample for analysis.

### 3.6

#### Procedures for Analyzing Samples.

Sorbent tube PSDs were analyzed on the Perkin Elmer Autosystem GC system, which includes the Automatic Thermal Tube Desorber (ATD-400) and the Turbochrom data acquisition system. Tubes were desorbed on the ATD-400 for 5 minutes at 250°C onto the cold trap of the ATD-400. The cold trap was then heated rapidly to 250°C and held there for 2 minutes to flush the sample from the cold trap and send it directly to the GC. The sample was separated on the GC column, which was a 15-m, 0.53 mm ID, 3.00 µm film thickness, fused Silica Capillary column Supelco model SPB-1. The column was held at 100°C for 1 minute, heated to 150°C at a rate of 10 °C/min, and then heated to 200 °C at a rate of 25°C/min (MS eluted from the column at 2.11 minutes). The gases from the column were sent to the detector, a Flame Ionization Detector (FID), which measured the number of ions given off (in millivolts) and transmitted the data to the Turbochrom computer data acquisition system, which graphs voltage (millivolts) versus time (minutes). The computer then integrated the area beneath the peaks to determine the mass of each individual component in terms of ng.

The Turbochrom data system was calibrated by injecting chemical standards of known concentrations (MS in isopropanol) onto cleaned sorbent tubes and analyzing them on the ATD-400/Autosystems GC system. The data system calibration uses a linear regression equation. A calibration graph is shown in Appendix A. Quality Control checks were performed each test day to ensure that the GC was functioning properly. Injections of standards were made throughout the mass range that was anticipated to be analyzed. Tubes were not analyzed if the QC checks showed a deviation greater than 10% from the mass injected.

### 3.7

#### Quality Assurance/Quality Control Procedures.

Tenax sorbent provided to the manufacturer of the PSDs was purified and certified clean by an independant laboratory at Pennsylvania State College. The purification process involved supercritical liquid extraction followed by heating and purging with carrier gas. The adsorbent was then sampled and analyzed by gas chromatograph analysis to ensure adequacy of the cleaning; strict purity protocol requirements were followed.

Following receipt of the samplers from the manufacturer, the sorbent was sampled again at the ERDEC lab. One sampler from each lot was analyzed for verification by removing the sorbent, placing it in a sorbent tube and analyzing the tube for residual levels of MS with the GC.

Quality control (QC) checks were performed each test day to ensure that the gas chromatograph was properly calibrated (calibration data are shown in Appendix A). Standard solutions containing known quantities of MS were used to verify that the mass of MS adsorbed by the PSDs was detected accurately.

The MIRAN© was used to control the level of MS vapor in the chamber and was calibrated before the testing. Calibration data for the MIRAN© is also included in Appendix A.

During each pre- and post-trial period in which the PSDs were being mounted, removed, and transferred to sorbent tubes in clean room area, three PSDs designated as "open blanks", were removed from their storage containers and exposed to the clean-room environment. These samples were analyzed to measure background levels of MS present during instrumentation, dressing, doffing, and removal of samplers and not related to the exposure in the chamber.

#### 4. METHOD OF ANALYSIS

##### 4.1 PSD Concentrations and Protection Factors.

The concentration of MS ( $C_{ms}$ ) sampled by each interior PSD was calculated by dividing the total mass of MS on each PSD measured in the GC analysis (ng) by the product of the sampling rate of the PSDs (in  $\ell/min$ ) multiplied by the total sampling time of each PSD (in minutes) (see equation 1). The averaged mass from the open background PSD samples was subtracted from each samples' mass before calculating the concentration to correct for incidental exposure of the PSDs during donning, doffing, transfer, and storage. Background samples were exposed to the air inside the clean room during the entire dressing/undressing/PSD removal time. The PSD concentration for each body area was calculated using the following equation:

$$C_{ms} = \frac{\text{Mass of MS from PSD} - \text{Mass of MS from Background}}{\text{Sampling Rate of PSD} \times \text{Exposure Time}} \quad (1)$$

Each PSD concentration was converted to a dosage by multiplying by the exposure time. The concentration of MS in the chamber was averaged from the MIRAN<sup>©</sup> data file and the total exposure dosage during each trial was calculated by multiplying by the exposure time. This value was used in the calculations of the protection factor (PF) at each body area.

Individual PFs were determined by dividing the exposure dosage by the dosage detected inside the suit at each location. The PF calculation is expressed mathematically in equation 2:

$$PF = \frac{\text{Average Exterior Concentration} \times \text{Time}}{\text{Average Concentration Inside Suit} \times \text{Time}} = \frac{\text{Exterior Dosage}}{\text{Dosage Inside Suit}} \quad (2)$$

The PF values were tabulated for each different body area.

The mass analyzed from each PSD was examined to determine if it was significantly different from the mass of the averaged background samples. This process was performed by subtracting the averaged background mass plus one standard deviation (of the average) from the mass of each PSD and determining if the result was greater than zero. If the resulting mass was greater than zero, then the analysis methods outlined above were performed. If the resulting mass was less than zero, then the PSD was considered not to have sampled any MS during the exposure period and the maximum PF for that test was assigned for that PSD sample. The maximum PF for each test was determined by dividing the challenge dosage that the test subjects were exposed to by the minimum dosage capable of being analyzed by the gas chromatograph.

The smallest detectable amount of MS that can be measured with the combined PSD/gas chromatograph system during these tests was determined by measuring the variability of analyzed samples. This variability was measured in a study that determined the overall background mass of MS on 25 unopened, unused PSDs. In this study, 25 unused PSDs were packed in sample tubes and analyzed. There was very little difference between the readings obtained in this background sample study and the average background masses determined in the MIST tests. The average background mass on these samples was 113.46 ng with a standard deviation of only 3.60 ng. The standard deviation of these samples is the value that was used as the smallest detectable mass of MS on the PSD/GC system. Based upon an average challenge concentration of 50 mg/m<sup>3</sup>, a 30-minute exposure period, and a PSD sampling rate of 14.6 cm<sup>3</sup>/min, the equations listed above yield a maximum detectable PF of around 8000. This value varied from test to test depending on the total exposure dosage each subject was exposed to. The range of maximum PFs calculated in these tests was between 6500 to 10000.

#### 4.2 Calculation of Overall Protection Factors.

The overall PF of the suit was determined by using the Body Region Hazard Analysis (BRHA) process developed by Fedele and Nelson<sup>1</sup>, which is based upon the amount of agent that must be absorbed percutaneously (through the skin) in each of 23 different body areas to produce mean, end-point reactions. In the model, the mean end-point reaction is taken as the first significant symptom that occurs as a result of exposure to the agent. For nerve agent (O-ethyl S-[2-diisopropylaminoethyl] methylphosphono-thiolate - VX) exposure, it is miosis (constriction of the pupil of the eye) that occurs first. Reddening of the skin (similar to severe sunburn) is the mean, end-point reaction for exposure to blister agent mustard (Bis[2-chloroethyl] sulfide - HD). This model applies data obtained from adsorption studies on human skin with pesticides<sup>6</sup> and the nerve agent VX<sup>7</sup>. A weighting factor is assigned to each of these values based on the dose and the total percentage of that skin area.

The overall PF for nerve and blister agents requires separate calculations. For nerve agent, the overall PF is based on a weighted average of the PF measurements from all individual body areas. This approach is used because nerve agents produce a systemic rather than a localized response in the individual. When the overall PF for nerve agents is multiplied by 10 mg-min/m<sup>3</sup> (which is the minimum dosage of the nerve agent VX that an unprotected individual must adsorb through their skin to develop end-point reactions) the systemic Minimum Required Exposure Dosage (MRED) value is obtained.

The initial effects of blister agent are localized to specific body areas. Furthermore, the skin in each body area has a different level of sensitivity. Consequently, the overall PF for the blister agent HD is expressed as a localized MRED. This is calculated by multiplying a local exposure dosage, which quantifies the sensitivity of the skin at a particular body region, by the PF measured at that region. The *lowest* calculated localized MRED value is applied in evaluating the suit and is reported (along with the skin area affected) in evaluating the protective capability of the suit and areas of susceptibility.

A detailed description of both of these methods and equations used to calculate overall PF using the Fedele BRHA process is contained below.

#### 4.2.1 Systemic Effect - Nerve Agent (VX).

The BRHA process quantifies the dosage required to cause a systemic nerve agent effect (end-point reaction) for each body area. These dosages are listed in Table 2 and are divided into the skin area to calculate the area/dosage (A/D) factor. The A/D factor equals the percentage of skin area divided by mass required to be absorbed at that area to produce the end-point reaction. The overall PF of the suit is determined by dividing the sum of the A/D factors by the sum of the A/(D\*PF) factors (A/D factor divided by PF at each area).

The equations used to perform each of these calculations are as follows:

$$(A/D)_i = A_i \div D_i \quad (3)$$

$$(A/(D \cdot PF))_i = A_i \div D_i \div PF_i \quad (4)$$

$$\text{Overall PF} = \frac{\sum (A/D)_i}{\sum A/(D \cdot PF)_i} \quad (5)$$

where  $PF_i$  is the protection factor measured at location  $i = 1, 2, \dots, 23$ , and PF is the overall protection factor summed over  $i = 1, 2, \dots, 23$  body areas. Because this portion of the Fedele model was developed using data taken from controlled human exposure to the nerve agent VX, the overall PF was then multiplied by the minimum dosage of VX that an unprotected individual must be exposed to in order to develop end-point reactions (miosis of the eyes occurs first). That dosage is  $10 \text{ mg-min/m}^3$ . This factor is called the Systemic MRED, and is used to predict dosage exposure required for systemic nerve agent effects.

#### 4.2.2 Localized Effect - Blister Agent (HD).

A second data set from the BRHA process was used to determine what exposure dosages are required to cause end-point reactions when the suit wearer is exposed to HD vapor (reddening of the skin occurs first, similar to severe sunburn). Since the effects of HD are not cumulative and generally affect only localized body regions, the model predicts MREDs for each body region (based upon the individual PF values); and the lowest value of all these dosages is used to predict the lowest response dosage for people using the Responder. Listed in Table 2 are the local exposure dosages for HD provided by the model. The Local Exposure Dosage column in Table 2 contains values of agent dosages (LEDs) to which each individual skin area must be exposed to in order to attain a localized skin reaction. These values were multiplied by the appropriate PF value to obtain the MRED required to cause localized skin reactions at each body location. Thus, the localized MRED for the Responder was calculated using the following equation:

$$\text{Localized MRED} = (\text{LED}_i \cdot PF_i) \quad (6)$$

where LED is the localized exposure dosage for skin area  $i = 1, 2, \dots, 23$ , and PF is the protection factor measured at skin area  $i = 1, 2, \dots, 23$ . The site with the lowest value is used in the evaluation of the data for the tests, i.e., the site with the smallest MRED value was the area least protected by the Responder.

Table 2. Model Parameters used to Calculate the Overall Protection Factor

Sample Region	PSD Sample Number	Skin Area (cm <sup>2</sup> )	VX Dose mg/ind	A/D Factor	Local Exposure Dosage for HD mg-min/m <sup>3</sup>

## 5. RESULTS AND DISCUSSION

Results of the testing of the Responder CSM® suit are summarized in Table 3. Table 4 lists the average challenge concentration and dosage during each trial for both pairs of subjects and the average concentration inside the clean room during each test. Complete test data (including the BRHA process calculation parameters and the summarized data from the DAS) are listed in Appendix B for the four trials conducted. Table 3 lists the test conditions, overall PF against nerve agent (VX), the systemic MREDs for nerve agent (VX), and the localized MREDs (for skin reactions to mustard) along with the skin area corresponding to the lowest localized MRED.

The Systemic MREDs correspond to the systemic dosage an individual must be exposed to in order to exhibit the first symptoms of agent exposure. This first symptoms are headache or miosis (pinpointing of the eyes) and are not severe reactions. It was suggested that the more severe reaction of nausea and vomiting be used in calculating the Systemic MREDs (this would use a value of 25 mg-min/m<sup>3</sup> instead of 10 as

the exposure dosage) so that a more realistic value (of what dosage a suit wearer must be exposed to before effects would occur) would be obtained. The original headache/miosis symptom was still used in these calculations, however, and this provides a very conservative estimate of exposure dosages that would cause effects. Multiplying the Systemic MRED by 2.5 will yield the value that the suit wearer must be exposed to in

		2	60.15	1865.	0.000016

order to develop the more severe reactions. The localized MRED data was analyzed to determine the most vulnerable areas in the protective ensemble, that is, the areas in which mustard would redden the skin first. All MRED values reported hereinafter have the units of mg-min/m<sup>3</sup>; PF values are unitless.

The average values for all the trials was calculated. Statistical data was analyzed to determine the standard deviation and the 90 and 95% confidence intervals for this data. This analysis indicates that the overall PF for 90% (or 95%) of the suits will fall between the average values plus or minus this value. The results of this testing on the Responder CSM® suit and SCBA respirator showed that the combined ensemble provided an average overall protection factor of  $1686 \pm 317$  (90% confidence interval) when the data is analyzed for all sizes of the suit. The Systemic MRED was  $16863 \pm 3165$ . The Localized MRED was  $127943 \pm 38361$ .

The data from the individual suit sizes was analyzed independently to determine the protection of each size. This data showed that the small size suits had an average overall protection factor of  $1247 \pm 648$  (90% confidence interval), a Systemic MRED of  $12473 \pm 6479$ , and a Localized MRED of  $101473 \pm 84487$ . The medium size suits had an average overall protection factor of  $2008 \pm 441$  (90% confidence interval), a Systemic MRED of  $20077 \pm 4409$ , and a Localized MRED of  $158347 \pm 54813$ . The large size suits had an average overall protection factor of  $1279 \pm 553$  (90% confidence interval), a Systemic MRED of  $12786 \pm 5529$ , and a Localized MRED of  $59272 \pm 7848$ .

The lowest values of the Localized MREDs are usually indicators of the skin areas that are most vulnerable while wearing the suit. The data from all 14 suit tests were summarized in order to calculate the average value of the Localized MRED for each body location throughout all of the trials. The minimum, the maximum, the sample standard deviation, and the 95% confidence interval were also calculated. The values for these calculations are listed in Table 5 below, and the summary is graphically presented in Figure 6. The body regions that were most vulnerable in this testing were predominantly very sensitive regions of the body, and included the Scrotum, the Chin & Neck, the Ears, and the Cheeks & Neck regions. Generally these areas were still very well protected, with

the average dosage required to cause effects at the most sensitive region (the Scrotum) while wearing the suit ensemble being over 164,000 mg-min/m<sup>3</sup>. There was really no significant difference between the other individual skin areas in this suit. The areas that did show the lowest MREDs are all very highly sensitive areas of the body and adsorb agent at higher rates than more durable skin areas (such as the forearm). This is the reason certain skin regions consistently have lower values, not because there is any significant vulnerability areas of this suit at these locations. Based on these test results, it is very unlikely that wearers would ever experience any effects while wearing these suits in chemically contaminated environments because all of the values, including the Overall PF, the Systemic and the Localized MREDs were very high. A wearer would have to be exposed to a very large amount of agent in order to be affected.
